四、醫囑判讀（每題 1 分，共計 5 分）

1. MgO 2# po p.c. tid
2. Scanol 1 # po p.c. qid
3. Ativan 1# po h.s. qd
4. If BT>39.5°C , Voltaren 1 # supp q6h prn
5. Foley training q2h

五、病歷摘要 (英翻中, 20 分/題)

This 56-year-old male is a non-smoker with medical history of HTN and hyperuricemia, regularly follow-up at our OPD. This time, he suffered from hemoptysis with minimal blood-tinged sputum since this April. The symptom was subsided soon later without medical treatment. However, hemoptysis occurred again 2 weeks ago and cough up with a tissue-like material last week, bloody sputum ensued. He visited our chest OPD on June 07, where chest radiograph showed left hilum nodules. Chest CT was arranged and disclosed multiple masses and nodules in bilateral lung fields. Besides, high CEA level(118.3) also detected. One set of sputum AFS was negative. Under the impression of r/o lung cancer, he was then admitted for tissue proof and staging work-up.
